## REVISION HISTORY

### Revision 6, Version 3.0, October 2016

This revision provides the calibration changes applied to PPS Version 05 products. All information including tables and figures is in Section 12 (Appendix H), Changes From Version 04 to Version 05.

The Data Calibration Handbook, revision H provided by BATC was the origin of most of the calibration changes for V05. Details of the analysis that led to the preparation of the revision H handbook were conducted by Remote Sensing Systems personnel and David Draper at BATC. Details of this analysis can be obtained from Wentz and Draper (2016). *See references for details of the paper.*

### Revision 5, Version 2.3, February 2016

In this revision, the following describes the calibration changes from Version 03 (V03) GPM Microwave Imager (GMI) Level 1B (L1B)/Base to Production Version 04 (V04) GMI L1B/Base.

1. Adjustment of spillover coefficients of all GMI channels. This adjustment is the major improvement from V03 to V04 in GMI antenna pattern correction (APC). The adjustment of spillover is based on the data from GMI inertial hold and refinements of the analysis performed by the GMI manufacturer. Table 2.12 shows comparisons of APC coefficients reflecting the changes due to spillover adjustments. Brightness temperature ( $T_b$ ) changes vary from channel to channel and are functions of brightness temperatures. Figure 2.32 demonstrates the  $T_b$  changes for all channels in their normal temperature range. For channels 1-5,  $T_b$  reduced ~3 – 6 K at their maximums. For channels 10-13,  $T_b$  increased ~2 – 4 K at their maximums. For channels 6-9,  $T_b$  increased ~0.1 K at their maximums.
2. Adjustment of antenna-induced along-scan bias correction. This is a minor adjustment and may result in  $T_b$  changes of less than 0.1 K.
3. Adjustment of magnetic correction coefficients. This is also a minor adjustment and may result in  $T_b$  changes of less than 0.1 K.

All of these corrections are implemented in V04 GMI L1B/Base as well as Integration and Testing Environment 043 (ITE043) and ITE057. There were no code adjustments for these updates.

### Revision 4, Version 2.0, December 2015

In this revision, using additional post-launch deep-space maneuver data, Ball Aerospace and Technologies Corporation (BATC)/Remote Sensing Systems (RSS) revised antenna pattern correction coefficients for some of the channels (Section 2.2). A Noise Equivalent Delta Temperature (NEDT) computation was also added in Section 2.5.

### Revision 3, Version 1.0, September 2014

In this revision, using post-launch deep-space maneuver data, BATC/RSS provided an algorithm to correct errors induced by instrument susceptibility to magnetic fields (Section 2.4). There were also along-scan corrections on main reflector antenna patterns (Section 2.2). Post-launch validation (Section 2.5) was revised to include analyses of GMI antenna temperature ( $T_a/T_b$ ) data in the September 2014 public release. Algorithms for detecting radio frequency interference (RFI) on cold load were also revised (Section 2.1.5). In Section 1, spectrum response charts for all channels were added.

### **Revision 2, Version 0.4, June 2014**

In this revision, the GMI L1B algorithms were updated with new Ball sensor data and code updates for the public release on June 16, 2014. Sections 2.1.5 and 2.1.6 were updated accordingly to comply with the algorithm updates, including new Table 2.9, Maximum values for correction code computation, and new Figure 2.5, Sample GMI 10 GHz V channel  $T_a$  (upper) and 166 GHz V channel  $T_a$  (lower).

### **Revision 1, Version 0.3, April 2014**

In this revision, post-launch studies from BATC/RSS provided new tables of on-orbit hot/cold sample ranges (Table 2.4, Hot load sampling, and Table 2.6, Cold sky sampling). Non-linearity look-up tables (Appendix A) and diode excess temperature look-up tables (Appendix C) were updated, and the number of scans to be averaged in multi-scan calibration was also revised (Section 2.1).

## 1. INTRODUCTION

### 1.1 OBJECTIVE

This document describes the GMI Level 1B algorithm developed by PPS. It consists of physical bases and mathematical equations for GMI calibration, as well as after-launch activities. The document also presents high-level software design. Parts of this document are from the Remote Sensing Systems (RSS) GMI Calibration ATBD and the BATC Calibration Data Book as contributed by the BATC GMI manufactory contract. The GMI L1B geolocation algorithm is described in a separate Geolocation Toolkit ATBD.

### 1.2 INSTRUMENT DESCRIPTION

GMI is a conically scanning microwave radiometer on board the GPM core satellite. The core satellite flies in a 407-km circular orbit with a 65° inclination angle. The GMI has 13 channels at frequencies of 10.65, 18.7, 23.8, 36.64, 89, 166, and 183.31 GHz. Except the heritage hot load and cold load that are commonly used for linear sensor radiometric calibrations, hot noise diodes and cold noise diodes are implemented in the GMI to determine the non-linearity and noise levels of the measurements. Figure 1.1 and Figure 1.2 show the main components of the GMI.

Figure 1.1. GMI instrument stowed configuration; provided by BATC.

**Figure 1.2. GMI instrument deployed configuration; provided by BATC.**

Key GMI sensor data include:

Nominal altitude: 407 km  
Orbital inclination: 65 deg  
Spin rate: 32 rpm  
Scan time: 1.875 sec  
Earth swath width: 885 km  
Earth viewing sector: 145 deg  
Earth samples: 221  
Integration time: 3.6 msec  
Dish size: 1.22 m

The GMI 1Base file also includes antenna temperature of full rotation swaths (about 500 samples). Some of the important sensor specifications can be found in Table 1.1.

**Table 1.1. Reference for important instrument and orbital parameters.**

Channel #	Center Frequency (GHz)	Pol	Nadir Angle (Degree)	Earth Incidence Angle (Degree)	Beam Width (Degree)	Footprint (km×km)	Cold Samples per Scan	Hot Samples per Scan	Earth Samples per Scan	Band-width (MHz)
1, 2	10.65	v/h	48.5	52.821	1.72	32.1×19.4	19/25	13/19	211/221	100
3, 4	18.7	v/h	48.5	52.821	0.98	18.1×10.9	31/37	13/19	211/221	200
5	23.8	v	48.5	52.821	0.85	16.0×9.7	31/37	13/19	211/221	400
6, 7	36.64	v/h	48.5	52.821	0.81	15.6×9.4	45/51	19/25	211/221	1000
8, 9	89	v/h	48.5	52.821	0.38	7.2×4.4	45/51	25/31	211/221	6000
10, 11	166	v/h	45.36	49.195	0.37	6.3×4.1	45/51	27/33	211/221	4000
12	183.31 ±3		45.36	49.195	0.37	5.8×3.8	45/51	27/33	211/221	2000
13	183.31 ±7		45.36	49.195	0.37	5.8×3.8	45/51	27/33	211/221	2000

For a number of samples, the first is for radar blanking on and the second is for radar blanking off. However, the cold and hot sample tables were revised after launch (see Table 2.6 and Table 2.4 for the best samples used in calibration).

Figure 1.3 to Figure 1.15 demonstrate the typical spectral response of the 13 GMI channels.

### 1.3 L1B ALGORITHM OVERVIEW

The Level 1B algorithm and software transform Level 0 counts into geolocated and calibrated antenna temperatures ( $T_a$ ) and brightness temperatures ( $T_b$ ).  $T_a$  is obtained by utilizing the sensor radiometric calibration as well as various corrections based on after-launch analyses.  $T_b$  is derived from  $T_a$  after antenna pattern correction (APC) and along-scan corrections. Figure 1.16 describes the relationship between algorithm components and products (or output).

Figure 1.16. The top-level flow chart of the GMI L1B algorithm.

### 1.4 L1B DATA DESCRIPTION

The standard Level 1B GMI data are geolocated and calibrated microwave antenna temperature ( $T_a$ ) and brightness temperature ( $T_b$ ) in two separate data files. The base  $T_a$  data file (GMIBASE) includes all calibration parameters and measurements that are used to generate  $T_a$  and all navigation parameters that are used to “geolocate” the pixel. The base  $T_a$  data file also includes two full scan swaths. Four geolocated swaths in GMIBASE are as follows:

1. Low-frequency swath (S1, channels 1-9, 221 pixels).
2. High-frequency swath (S2, channels 10-13, 221 pixels).
3. Full low-frequency swath (S3, maximum 500 pixels).
4. Full high-frequency swath (S4, maximum 500 pixels).

The  $T_b$  data file (1BGMI) includes all parameters for corrections of  $T_a$ . 1BGMI only has S1 and S2 swaths. Both GMIBASE and 1BGMI include sufficient information to reverse the calibration process.

Standard L1B data are in the format of a full orbit (about 90 minutes). Realtime L1B data are processed in a 5-minute time period.

## 2. CALIBRATION ALGORITHM

### 2.1 RADIOMETRIC CALIBRATION

The GMI sensor spins continuously. In each complete rotation, the sensor measures Earth radiation in a section of 140 degrees. Beyond 140 degrees up to 145 degrees, the sensor may also take valid Earth measurements if applicable. The other section of the rotation is used for calibration purposes. For channels 1-7, operational GMI has a calibration cycle that repeats every two scan rotations. In the first scan rotation, noise diodes are turned off and the cold sky and the hot load are sampled for the purpose of radiometric calibration. In the second rotation, noise diodes are turned on and the cold sky plus noise diode and hot load plus noise diode are sampled for 10-37 GHz channels. The two-scan calibration cycle provides four calibration points to calculate not only the gain and offset of the receivers, but also the excess noise temperature of the noise diodes and the nonlinearity of the receivers. For other channels (89 GHz to 183 GHz), all scans have a scan-by-scan calibration cycle (collecting hot and cold calibration data only for all scans). The calibration assembly configuration is shown in Figure 2.1. Cold sky reflector and hot load are stationary. They do not rotate with the instrument. The hot load tray mounts to the deck and rotates with the instrument.

**Figure 2.1. Calibration assembly configuration; taken from BATC data book.**

The GMI uses a non-linear three-point in-flight calibration to derive antenna temperature. The four-point calibration is used to monitor the sensor non-linearity and to calibrate when hot load measurements are not available for the 10-36 GHz channels.

#### 2.1.1 Non-linear Radiometric Calibration

If the transfer function is perfectly linear, two calibration points (hot and cold loads) would uniquely determine the state of the Earth observation. However, in reality, they are slightly nonlinear. Figure 2.2 shows a schematic diagram of the GMI nonlinear calibration approach as compared to the traditional linear calibration in the TRMM Microwave Imager (TMI).

**Figure 2.2. Schematic diagram of GMI non-linear calibration.**

Equation (2.1) shows the GMI non-linear calibration equation for each of the 13 GMI channels. This is a quadratic radiometric transfer function.

$$T_a = X * T_h + (1-X) * T_c - 4 * T_{nl} * X * (1-X) \quad (2.1)$$

where:

**T<sub>a</sub>**: antenna temperature for each pixel of the scan.

**T<sub>h</sub>**: mean hot load temperature of the scan; **T<sub>c</sub>**: mean cold sky temperature of the scan.

**T<sub>nl</sub>**: peak non-linearity generated from look-up table or computed from four-point calibration.

**X = (C - C<sub>c</sub>) / (C<sub>h</sub> - C<sub>c</sub>)**: radiometer response.

**C**: Earth view count of the pixel; **C<sub>c</sub>**: mean cold load count; **C<sub>h</sub>**: mean hot load count.

The PPS L1B algorithm uses a more conventional form (2.2) derived from the above basic equation (2.1) such that PPS will be able to trend gain, offset, and nonlinearity against the Earth view counts.

$$T_a = (b + b_{nl}) + (a + a_{nl})C + c_{nl}C^2 \quad (2.2)$$

**a = (T<sub>h</sub> - T<sub>c</sub>) / (C<sub>h</sub> - C<sub>c</sub>)**: gain in linear equation.

**a<sub>nl</sub> = -4 T<sub>nl</sub> (C<sub>h</sub> + C<sub>c</sub>) / (C<sub>h</sub> - C<sub>c</sub>)<sup>2</sup> = -ua<sup>2</sup> (C<sub>h</sub> + C<sub>c</sub>)**: gain due to non-linearity.

$$u = 4 T_{nl} / (T_h - T_c)^2 \quad (2.3)$$

**b = (C<sub>h</sub> T<sub>c</sub> - C<sub>c</sub> T<sub>h</sub>) / (C<sub>h</sub> - C<sub>c</sub>)**: offset in linear equation.

**b<sub>nl</sub> = ua<sup>2</sup> C<sub>h</sub> C<sub>c</sub>**: non-linear offset.

**c<sub>nl</sub> = ua<sup>2</sup>**: non-linear gain.

Look-up tables of **u** are provided by the sensor manufacturer as a function of receiver gain and receiver temperature (see Appendix A). Four-point calibration also computes the **u** in the

algorithm but outputs it in  $\mathbf{T}_{nl}$  format. All of these coefficients are written out in the data products such that one may easily retrieve the count back from  $\mathbf{T}_a$ . The algorithm can switch between equation (2.2) and equation (2.1). The nonlinearity term of equation (2.1) can be expanded as:

$$\begin{aligned}\mathbf{T}_a^{nl} = -4 * \mathbf{T}_{nl} * \mathbf{X}_i * (1 - \mathbf{X}_i) &= b_{nl} + a_{nl} \mathbf{C} + c_{nl} \mathbf{C}^2 = u \mathbf{a}^2 (\mathbf{C}_h \mathbf{C}_c - (\mathbf{C}_h + \mathbf{C}_c) \mathbf{C} + \mathbf{C}^2) \\ &= u \mathbf{a}^2 (\mathbf{C} - \mathbf{C}_h)(\mathbf{C} - \mathbf{C}_c)\end{aligned}\quad (2.4)$$

with tie points at  $\mathbf{C}_h$  and  $\mathbf{C}_c$  and maximum nonlinearity point at  $\mathbf{C} = (\mathbf{C}_h + \mathbf{C}_c)/2$ .

For a typical 36 GHz V channel with high gain, assume  $T_c=3K$ ,  $T_h=300K$ ,  $C_c=20351$ ,  $C_h=38104$ ,  $u=-2.388E-5$ . We can derive the maximum  $u \mathbf{a}^2 (\mathbf{C} - \mathbf{C}_h)(\mathbf{C} - \mathbf{C}_c) = 0.5266 K$  at  $\mathbf{C} = (\mathbf{C}_h + \mathbf{C}_c)/2 = 29772$ .

The nonlinearity is also calculated on-orbit by the four-point calibration method for 10-36 GHz channels. If nonlinearity drifts a statistically significant amount, the data can be updated using on-orbit trending.

### **2.1.2 Hot Load View**

The hot load consists of a non-rotating calibration target that intercepts the line-of-sight between the feed horns and the main reflector as the feed horns pass beneath the hot calibration load during each scan. The temperature of the hot load is passively controlled and will be between 240 K and 330 K over all on-orbit conditions. Figure 2.3 shows the GMI hot load calibration target. The load is sized to allow a minimum of four measurements per view for all channels. The hot load is sampled multiple times per rotation of the main reflector.

At a certain point and time, sunlight may strike the hot load and cause additional gradients that cause its effective temperature to deviate from what the platinum resistance thermometers (PRTs) read. The GMI hot load is designed to minimize such effect. However, it will still need to be analyzed during the post-launch calibration and validation.

**Figure 2.3. GMI hot load; taken from GMI PDR day 4-5: Calibration assembly (Randy Keller).**

### **Hot load temperature $T_h$ for scan $i_n$ :**

The mean hot load temperature for each scan is determined by the following equations:

$$\text{Resistance of the PRT: } R_T = (C_T - C_{lo})(R_{hi} - R_{lo})/(C_{hi} - C_{lo}) + R_{lo} \quad (2.5)$$

Resistances of high calibration resistor  $R_{hi} = 2800.08$  (preliminary), and low resistor  $R_{lo} = 1500.04$  (preliminary) for the 11 PRTs.

$C_T$ ,  $C_{hi}$ ,  $C_{lo}$  are raw counts of the PRT, high-calibration resistor, and low-calibration resistor retrieved from telemetry.

$$\text{Temperature of the PRT: } T_T = \sum_k a(k) R^k_T \text{ (in } ^\circ\text{C)} \quad (2.6)$$

Following is a table to show typical  $C_{hi}$ ,  $C_{lo}$ , and  $a(k)$  ( $k=0,1,2,3,4,5$ ). However,  $C_{hi}$ ,  $C_{lo}$  are actually read from telemetry for each scan and may deviate from their typical values.

**Table 2.1. PRT temperature coefficients.**

PRT#	$C_{hi}$	$C_{lo}$	$a(0)$	$a(1)$	$a(2)$	$a(3)$	$a(4)$	$a(5)$

### **Scan average and tray correction:**

Scan hot load temperature  $T_{Tave}$  ( $i$ ),  $i=1,2$ , is split into two categories.  $T_{Tave}$  (1) is averaged over PRT #1 and #8-10 for the use of 10, 166, and 183 GHz channels.  $T_{Tave}$  (2) is averaged over PRT #2 and #11-14 for the use of 18, 23, 36, and 89 GHz channels. PRT #7 (base) and PRT #15 are not used in calibration. Figure 2.4 demonstrates the geometry of the GMI hot load.

Figure 2.4. GMI hot load geometry.

### Correction using hot load tray temperature:

$$T_{h\text{scan}}(i) = w_0 + w_1 T_{T\text{ave}}(i) + u_0 + u_1(T_{T\text{tray}} - T_{T\text{ave}}(i)) + u_2(T_{T\text{tray}} - T_{T\text{ave}}(i))^2 + u_3(T_{T\text{tray}} - T_{T\text{ave}}(i))^3 \quad (2.7)$$

b(j),  $w_0, w_1, u_0, u_1, u_2, u_3$  for all channels are summarized in Table 2.2 (revised).

Table 2.2. Cubic correction coefficients for hot load temperatures.

$$\text{Resistance of the tray: } R'_T = (C'_T - C'_lo)(R'_hi - R'_lo)/(C'_hi - C'_lo) + R'_lo \quad (2.8)$$

Resistances of high calibration resistor  $R'_hi = 3157$  (preliminary), and low resistor  $R'_lo = 1195$  (preliminary) for the tray.

$C'_T$ ,  $C'_{hi}$ ,  $C'_{lo}$  are raw counts of the tray, high-calibration resistor, and low-calibration resistor retrieved from telemetry.

$$\text{Temperature of the tray: } T_T = \sum_k a(k) R^k \quad (\text{in } {}^\circ\text{C}) \quad (2.9)$$

Following is a table to show how typical  $C'_{hi}$ ,  $C'_{lo}$ , and  $a(k)$  ( $k=0,1,2,3,4,5$ ).  $C'_{hi}$ ,  $C'_{lo}$  are read from telemetry.

**Table 2.3. Tray temperature coefficients.**

$C'_{hi}$	$C'_{lo}$	$a(0)$	$a(1)$	$a(2)$	$a(3)$	$a(4)$	$a(5)$
58170.308	7706.137	-238.3771643	0.108516065	7.18387E-06	-1.12508E-09	8.5039E-14	2.92338E-18

#### Average over multi-scans:

Since the hot load counts are multi-scan averaged, it is preferable that the hot load temperature is averaged over the same number of scans.

$$T_h = \frac{\sum_i k(i) T_{h\text{scan}(i)}}{\sum_i k(i)}$$

$T_h$  are averaged over 16 scans for channels 1-4, index scan -7 to +8 scans, over 14 scans for channel 5, index scan -6 to +7 scans, over 12 scans for channels 6-7, index scan -5 to +6 scans, over 5 scans for channels 8-13, index scan and  $\pm 2$  scans.

**Hot load count for scan  $i_n$**  is determined by equation (2.10).

The hot load counts are corrected for errors induced by Earth's magnetic field before they are processed for calibration (see Section 2.4).

$$C_h = \frac{(\sum_i \sum_j k(i,j) C_{hot}(i,j))}{\sum_i \sum_j k(i,j)} \quad (2.10)$$

$j=1,2,3, \dots n_{hot}$ .  $n_{hot}$  is the number of hot samples of each scan for each channel.

$i = i_n - N_h, i_n - N_h + 1, i_n - N_h + 2, \dots, i_n + N_h$ .  $i_n$  is the scan number of the granule to be calibrated and  $2N_h + 1$  is the number of scans within the screen window.

The hot load sampling tables are shown as follows. However, the best table is used in the code.

**Table 2.4. Hot load sampling.**

Nominal Sample Table		Spare1 Sample Table		Best Samples to Use (Revised by or-orbit data)				
Frequency	Hot Start	Hot End	Hot Start	Hot End	Hot Start	Hot End	Hot Start	Hot End
10 GHz	272	282	269	285	273	283		
18 GHz	306	316	303	319	307	317		
23 GHz	306	316	303	319	306	318		
36 GHz	352	366	349	369	352	367		
89 GHz	327	346	324	349	325	347		
166 GHz	315	339	312	342	320	335		
183 GHz	329	353	326	356	330	350		

Collect data when the noise diode is off.

For channels 1-4,  $\mathbf{C}_h$  are averaged over 8 scans. If the diode is off for the index scan  $i_n$  (index scan):  $i_n, i_n \pm 2, i_n \pm 4, i_n \pm 6, i_n + 8$ . If the diode is on for the index scan:  $i_n \pm 1, i_n \pm 3, i_n \pm 5, i_n \pm 7$ . For channel 5,  $\mathbf{C}_h$  are averaged over 7 scans. If the diode is off for the index scan  $i_n$  (index scan):  $i_n, i_n \pm 2, i_n \pm 4, i_n \pm 6$ . if the diode is on for the index scan:  $i_n \pm 1, i_n \pm 3, i_n \pm 5, i_n + 7$ . For channels 6-7,  $\mathbf{C}_h$  are averaged over 6 scans. If the diode is off for the index scan  $i_n$  (index scan):  $i_n, i_n \pm 2, i_n \pm 4, i_n + 6$ . If the diode is on for the index scan:  $i_n \pm 1, i_n \pm 3, i_n \pm 5$ . For channels 8-13,  $\mathbf{C}_h$  is always averaged over five scans:  $i_n, i_n \pm 1, i_n \pm 2$ .

#### **Hot load + noise diode counts for scan $i_n$ :**

The hot load + noise diode counts are corrected for errors induced by Earth's magnetic field before they are processed for calibration (see Section 2.4).

$$\mathbf{C}_{hn} = (\sum_i \sum_j k(i,j) C_{hot+diode}(i,j)) / \sum_i \sum_j k(i,j) \quad (2.11)$$

Collect data when the noise diode is on.

For channels 1-4,  $\mathbf{C}_{hn}$  are averaged over 8 scans. If the diode is on for the index scan  $i_n$  (index scan):  $i_n, i_n \pm 2, i_n \pm 4, i_n \pm 6, i_n + 8$ . If the diode is off for the index scan:  $i_n \pm 1, i_n \pm 3, i_n \pm 5, i_n \pm 7$ . For channel 5,  $\mathbf{C}_{hn}$  are averaged over 7 scans. If the diode is on for the index scan  $i_n$  (index scan):  $i_n, i_n \pm 2, i_n \pm 4, i_n \pm 6$ . If the diode is off for the index scan:  $i_n \pm 1, i_n \pm 3, i_n \pm 5, i_n + 7$ . For channels 6-7,  $\mathbf{C}_{hn}$  are averaged over 6 scans. If the diode is on for the index scan  $i_n$  (index scan):  $i_n, i_n \pm 2, i_n \pm 4, i_n + 6$ . If the diode is off for the index scan:  $i_n \pm 1, i_n \pm 3, i_n \pm 5$ .

#### **Bad-case handling:**

The mean and variance of hot load counts and hot load + noise diode counts are computed for each granule. The algorithm takes mean  $\pm 3$  sigma (6 sigma if variance is small) as valid values. If certain scans are missing or invalid, the algorithm will continue to the next scan until the number of scans to be averaged is equal to the number described above for all channels. However, the maximum number of scans to be searched is 20. If there is no valid hot load information within  $\pm 10$  scans, the algorithm will perform linear interpolation using the closest scans before and after the index scan and set the calibration quality flag to non-zero (0 indicates good calibration). If there is no hot load information within 200 scans, the algorithm will either use the hot load backup algorithm if cold sky measurements are available, or else generate missing  $T_a/T_b$  data for this scan.

### **2.1.3 Cold Sky View**

The cold calibration point is provided by the cold sky reflector (CSR), which allows the feed horns to view targets with a temperature of approximately 2.7 K. The cold sky view is also sampled multiple times per rotation of the main reflector and over multiple rotations of the main reflector. Table 2.5 shows mean cold sky temperature  $T_c$  for all GMI channels.

**Table 2.5. Mean cold sky temperature  $T_c$  for all GMI channels.**

Frequency (GHz)	10.65	18.7	23.8	36.64	89.0	166.0	183.31
Cold Load Temperature	2.94	2.85	2.77	2.82	3.27	4.43	4.76

**Cold load counts for scan  $i_n$ :**

The cold load counts are corrected for errors induced by Earth's magnetic field before they are processed for calibration (see Section 2.4). The mean cold sky count is determined by equation (2.12).

$$C_c = (\sum_i \sum_j k(i,j) C_{\text{cold}}(i,j)) / \sum_i \sum_j k(i,j) \quad (2.12)$$

$j=1,2,3, \dots n_{\text{cold}}$ .  $n_{\text{cold}}$  is the number of cold samples of each scan for each channel.

$i = i_n - N_h, i_n - N_h + 1, i_n - N_h + 2, \dots, i_n + N_h$ .  $i_n$  is the scan number of the current scan to be calibrated and  $2N_h + 1$  is the number of scans within the screen window. Collect data when the noise diode is off. The cold load sampling tables are shown as follows. However, the best table is used in the code.

**Table 2.6. Cold sky sampling.**

Nominal Sample Table			Spare 1 Sample Table		Best Samples to Use*	
					(Revised based on on-orbit data)	
Frequency	Cold Start	Cold End	Cold Start	Cold End	Cold Start	Cold End
10 GHz	340	353	337	356	342	368
18 GHz	368	393	365	396	390	410
23 GHz	368	393	365	396	388	408
36 GHz	418	459	415	462	437	460
89 GHz	392	433	389	436	410	440
166 GHz	381	422	378	425	392	442
183 GHz	395	436	392	439	398	452

Collect data when the noise diode is off.

For channels 1-7,  $C_c$  is averaged over 5 scans. If the diode is off for the index scan  $i_n$  (index scan):  $i_n, i_n \pm 2, i_n \pm 4$ . If the diode is on for the index scan:  $i_n \pm 1, i_n \pm 3, i_n \pm 5$ . For channels 8-13,  $C_c$  is averaged over five scans:  $i_n, i_n \pm 1, i_n \pm 2$ .

**Cold load + noise diode counts for scan  $i_n$ :**

$$C_{cn} = (\sum_i \sum_j k(i,j) C_{\text{cold+diode}}(i,j)) / \sum_i \sum_j k(i,j) \quad (2.13)$$

The cold load + noise diode counts are corrected for errors induced by Earth's magnetic field before they are processed for calibration (see Section 2.4).

Collect data when the noise diode is on.

For channels 1-7,  $C_{cn}$  are averaged over 5 scans. If the diode is on for the index scan  $i_n$  (index scan):  $i_n, i_n \pm 2, i_n \pm 4$ . If the diode is off for the index scan:  $i_n \pm 1, i_n \pm 3, i_n \pm 5$ .

#### **Bad-case handling:**

The cold sky view is a more complex combination of sources than the hot load. Contributions other than from cold space come from reflections and emission from the instrument. There is also Earth view intrusion into the cold sky view primarily through the backlobe of the CSR. The backlobe looks at the main reflector, which sees the Earth. The CSR is tilted up at an angle sufficient that little contamination comes from the Earth directly.

Due to the orbital and cold sky view geometry, the Moon may intrude into the cold sky view. This lunar intrusion has been clearly observed by many other satellite microwave radiometers that employ cold sky calibration (SSMI, SSMI/S, TMI, AMSR, and WindSat). The calibration algorithm will remove as much as possible of the contaminations of the cold sky view.

The mean and variance of cold sky counts and cold sky + noise diode counts are computed for each granule (if Moon index is set, the value will be excluded to compute mean and variance). The algorithm takes mean  $\pm 3$  sigma (6 sigma if variance is small) as valid values. If certain scans are missing or invalid, the algorithm will continue to the next scan until the number of scans to be averaged is equal to the numbers described above for all channels.

However, the maximum number of scans to be searched is 20. If there is no valid cold load information within  $\pm 10$  scans, the algorithm will perform linear interpolation using the closest scans before and after the index scan and set the calibration quality flag to non-zero (0 indicates good calibration). If there is no cold load information within 400 scans, the algorithm will generate missing  $T_a/T_b$  data for this scan.

#### **2.1.4 Nonlinearity**

Nonlinearity is determined by receiver gain and receiver temperature. Receiver gain is read from telemetry and determined by the following table.

**Table 2.7. Receiver gain settings.**

Channels	low gain	normal gain	high gain
10 GHz	6	4	2
18 GHz	6	4	2
23 GHz	6	4	2
36 GHz	6	4	2
89 GHz	6	4	2
166 GHz	4	2	1
183 GHz	5	4	3

Receiver temperatures are retrieved using a similar way of retrieving tray temperature.

$$\text{Resistance of the receiver: } R'_T = (C'_T - C'_{lo})(R'_{hi} - R'_{lo})/(C'_{hi} - C'_{lo}) + R'_{lo} \quad (2.14)$$

Resistances of high-calibration resistor  $R'_{hi} = 3157$  (preliminary), and low-calibration resistor  $R'_{lo} = 1195$  (preliminary) for the tray.

$C'_T$ ,  $C'_{hi}$ ,  $C'_{lo}$  are raw counts of the tray, high-calibration resistor, and low-calibration resistor retrieved from telemetry.

$$\text{Temperature of the receiver: } T_{\text{receiver}} = \sum_k a(k) R'_T \text{ (in } ^\circ\text{C)} \quad (2.15)$$

Following is a table to show typical  $C'_{hi}$ ,  $C'_{lo}$ , and  $a(k)$  ( $k=0,1,2,3,4,5$ ).  $C'_{hi}$ ,  $C'_{lo}$  are read from telemetry.

**Table 2.8. Receiver temperature polynomial coefficients.**

Freq	$C'_{hi}$	$C'_{lo}$	$a(0)$	$a(1)$	$a(2)$	$a(3)$	$a(4)$	$a(5)$
10GHz	58170.308	7706.137	-235.8509438	0.099626991	1.74703E-05	-6.44468E-09	1.37026E-12	-1.1467E-16

36GHz	58170.308	7706.137	-236.2001883	0.100808265	1.64408E-05	-6.03744E-09	1.29008E-12	-1.08434E-16
36GHz	58170.308	7706.137	-236.0667138	0.100417622	1.67243E-05	-6.14661E-09	1.31071E-12	-1.09965E-16
89GHz	58170.308	7706.137	-236.1859287	0.100662332	1.65911E-05	-6.10118E-09	1.30393E-12	-1.09648E-16
166GHz	58170.308	7706.137	-236.2362645	0.100930691	1.63367E-05	-6.00249E-09	1.28482E-12	-1.08198E-16
183GHz	58170.308	7706.137	-236.1070635	0.100466029	1.67138E-05	-6.13536E-09	1.30677E-12	-1.09468E-16

Look-up tables of  $\mathbf{u}$  are provided by the sensor manufacturer as a function of receiver gain and receiver temperature (see Appendix A) for all channels.  $\mathbf{u}$  is also computed from the four-point algorithm for trending and comparisons.

## 2.1.5 Moon and RFI Corrections

### Moon Correction:

The geolocation tool computes the Moon vector  $\mathbf{V}_{\text{moon}}$  for each scan in the GMI coordinate system (GICS). The algorithm computes the angle ( $\theta$ ) between Moon vector and cold beam pointing vectors  $\mathbf{V}_{\text{cold}}$  in the GICS for all cold view samples.

$$\cos\theta = \mathbf{V}_{\text{moon}} \cdot \mathbf{V}_{\text{cold}} / (|\mathbf{V}_{\text{moon}}| |\mathbf{V}_{\text{cold}}|) \quad (2.16)$$

$$= [ \mathbf{V}_{\text{moon}}(\mathbf{x}) \cdot \mathbf{V}_{\text{cold}}(\mathbf{x}) + \mathbf{V}_{\text{moon}}(\mathbf{y}) \cdot \mathbf{V}_{\text{cold}}(\mathbf{y}) + \mathbf{V}_{\text{moon}}(\mathbf{z}) \cdot \mathbf{V}_{\text{cold}}(\mathbf{z}) ] / \{ [ (\mathbf{V}_{\text{moon}}(\mathbf{x})^2 + \mathbf{V}_{\text{moon}}(\mathbf{y})^2 + \mathbf{V}_{\text{moon}}(\mathbf{z})^2)^{1/2} ] [ (\mathbf{V}_{\text{cold}}(\mathbf{x})^2 + \mathbf{V}_{\text{cold}}(\mathbf{y})^2 + \mathbf{V}_{\text{cold}}(\mathbf{z})^2)^{1/2} ] \}$$

If  $\theta < 6$  degrees, the algorithm sets the Moon index to non-zero and the cold sample is excluded for calibration. If the Moon index is set for a large section of the swath ( $> 20$  scans), the algorithm will use valid scans before and after the event to perform linear interpolation.

Appendix B provides the look-up tables of cold beam pointing vectors (revised). The following figures show an example of Moon flags, and scan averaged cold counts before correction and after correction. Figure 2.5 is the index from production for low-frequency swath channels. The value of index is the number of cold samples contaminated by the Moon's light. The intrusion occurred around scans 2200 to scans 2400 for 18, 23, 36, and 89 GHz channels. Figure 2.6 shows

the spikes of mean cold counts around this area before corrections. Figure 2.7 shows the results from the current version, and the spikes due to Moon intrusion are removed.

**Figure 2.5.** Moon flags for S1, indicates Moon intrusions onto 18 GHz to 89 GHz channels.

**Figure 2.6.** Scan cold counts of 36 GHz H channel with no Moon correction in V01D data.

**Figure 2.7.** Scan cold counts of 36 GHz H channel with Moon correction in V03A data.

### **RFI Correction:**

There are two RFI flagging methods in the algorithm. One is a simple limit check based on minimum cold count of the scan assuming that the intrusion is only to part of the cold sample sections. If the whole scan is contaminated, the scan is labeled as bad calibration and will be handled by bad-case handling as described in Section 2.1.3.

The simple limit check method first determines the lowest value from all cold samples of a scan. The code then computes the maximum cold count value derived from the following table:

**Table 2.9. Maximum gradients of cold counts within each scan.**

Channels:	1	2	3	4	5	6	7	8	9	10	11	12	13
Cold Offset	130	122	118	132	78	78	78	78	198	198	198	198	198
Cold + NoiseD Offset	240	232	202	198	122	116	112						

Maximum value = Lowest value + offset. If a cold sample within this scan is larger than the maximum value, it will be flagged (to non-zero). This method tends to under-flag the radio frequency interference (RFI) cold samples by about 20%.

The other method is based on the iterative mean comparison/dilation method. The method is quite complicated and has the following steps:

Step 1: Scan averaging – Create a scan average, ignoring data that already have been flagged. On the first iteration, all data will be included. First, the data are averaged over the cold samples within each scan; then, multiple scans are averaged together. For channels with noise diodes, this is done separately for the cold and cold + noise scans. In this version, three effective scans are used for all channels.

Step 2: Removal of scan average – For each sample within the each scan, the scan average from step 1 is removed.

Step 3: Cold swath flattening – This is done for each along-scan cell position by taking the median across all scans of the orbit. The computed variation is then subtracted from the result of step 2. This step provides additional sensitivity by removing scan-repeating variations.

Step 4: Thresholding – All cold samples from the result of step 3 are compared to a pre-determined threshold for each channel and noise diode state (Table 2.10). Data exceeding the threshold or that have been flagged on a previous iteration are flagged.

Step 5: Robust dilation – This step widens and fills in the flagged region. For each cell, if at least  $k$  cells in the surrounding  $m \times n$  region are flagged, then that cell is additionally flagged. If less than  $k$  cells are flagged, then the cell is set to unflagged. This method will unflag spurious noise measurements, allowing the user to set the thresholds in step 4 below 3-sigma, providing higher sensitivity.

Step 6: Iterate – Repeat steps 1-5 for a specified number of iterations.

**Table 2.10. Cold counts threshold of second RFI flagging method.**

Channel	Cold count threshold	Cold+noise count threshold	Cold scan average scans	Number of Iterations	Dilation window ( $m_{samp} \times n_{scan}$ )	Dilation number of samples threshold ( $k$ )
10V	24.0	62.0	3	3	3 x 15	5
10H	24.7	62.0	3	3	3 x 15	5
18V	27.3	57.4	3	6	3 x 15	5
18H	25.0	55.1	3	6	3 x 15	5
23V	23.9	40.0	3	3	3 x 15	5
36V	22.9	36.8	3	3	3 x 15	5
36H	22.9	36.3	3	3	3 x 15	5
89V	22.6		3	3	3 x 15	5
89H	21.0		3	3	3 x 15	5
166V	56.8		3	3	3 x 15	5
166H	55.1		3	3	3 x 15	5
183VA	54.5		3	3	3 x 15	5
183VB	49.0		3	3	3 x 15	5

The second method with the chosen thresholds tends to over-flag the cold sample about 20-30%. The algorithm actually uses both flagging methods to determine the final flagging value of a cold sample. If a sample is flagged (to non-zero) by the first method, the sample is flagged as an RFI sample. If a sample is flagged by the second method but not by the first method, the code searches a window of 15 samples by 61 scans to see if any of the cold samples in the window are flagged by the first method. If one or more cold samples within the window are flagged by the first method, the sample is flagged; otherwise, the sample is not flagged. If a cold sample is flagged, the sample is excluded from calibration.

The following figures show the results before and after the correction. Figure 2.8 is the index from production for the 18 GHz H channel. The total cold sample number is 21 for this channel. The intrusion occurred around scan 2400 to scan 2500. Figure 2.9 shows the spikes of mean cold counts around this area before corrections. Figure 2.10 shows the results from the current version, and the spikes due to warm RFI intrusion are removed.

Figure 2.8. Cold samples that are flagged as warm intrusions for 18 GHz H channel.

Figure 2.9. Scan cold counts of 18 GHz H channel with no correction in V01D data.

Figure 2.10. Scan cold counts of 18 GHz H channel with RFI correction in ITE001 data.

### 2.1.6 Earth View

A forward section of about  $145^\circ$  is used to view the Earth targets. The normal data have 221 samples for each scan. However, in cases when the data beyond  $140^\circ$  are useful, one scan may have more than 221 pixels. The data beyond the normal Earth view range can be retrieved from GMIBASE full rotation antenna temperatures. Due to the difference of incidence angles between lower frequency (channels 1-9) and high-frequency (channels 10-13) channels, the swath widths, as well as the geolocations of the two groups, are different. Figure 2.11 shows antenna temperatures of 10 GHz V (low-frequency swath) and 166 GHz V (high-frequency swath) channels.

**Figure 2.11. Sample GMI 10 GHz V channel  $T_a$  (upper) and 166 GHz V channel  $T_a$  (lower).**

There is RFI to the Earth view samples (for example, Figure 2.11 upper panel in England). Currently, the code flags Earth view pixels if  $T_b$  is greater than 325 K for all channels. The Earth view counts are corrected for errors induced by Earth's magnetic field before they are used to derive antenna temperature  $T_a$  (see Section 2.4).

### 2.1.7 Noise Diodes and Four-Point Calibration

The noise diodes are implemented for channels 1-7. These noise diodes are turned on every other scan such that additional calibration measurements are taken to perform four-point calibration to determine sensor nonlinearity. Figure 2.12 is the schematic diagram of four-point calibration.

**Figure 2.12. Schematic diagram of GMI four-point calibration.**

For cold load + noise diode measurement, the equation is:

$$T_{cn} = T_c + T_n = X_{cn}*T_h + (1-X_{cn})*T_c - 4*T_{nl} *X_{cn}*(1-X_{cn}) \quad (2.17)$$

where

$T_n$ : noise diode excess temperature.

$$X_{cn} = (C_{cn} - C_c) / (C_h - C_c).$$

$C_{cn}$ : cold load + noise diode count.

The equation is similar for hot load + noise diode measurement:

$$T_{hn} = T_h + T_n = X_{hn}*T_h + (1-X_{hn})*T_c - 4*T_{nl} *X_{hn}*(1-X_{hn}) \quad (2.18)$$

where

$$X_{hn} = (C_{hn} - C_c) / (C_h - C_c).$$

$C_{hn}$ : hot load + noise diode count.

The nonlinearity can be derived from equation (2.17) and (2.18):

$$T_{nl} = (T_h - T_c) / 4 * (X_{hn} - X_{cn} - 1) / (X_{hn} (1 - X_{hn}) - X_{cn} (1 - X_{cn})) \quad (2.19)$$

And then the  $T_n$  can be determined by either (2.17) or (2.18).

### 2.1.8 Back-up Calibration and Blanking Algorithm

Using  $C_{cn}$  and trended  $T_{cn} = T_c + T_n$  we may derive a hot load back-up algorithm in case there is no hot load information for a section with more than 20 scans.

The trended  $T_n$  can be derived from the look-up table as a function of diode temperatures (data can be found in Appendix C).

$$T_a = X_b * T_{cn} + (1-X_b)*T_c - 4*T_{nl} *X_b*(1-X_b) \quad (2.20)$$

$$\text{where: } X_b = (C - C_c) / (C_{cn} - C_c) \quad (2.21)$$

#### Blanking:

If blanking is on, the following correction is made to derive a corrected Earth count  $C_{corr}$ :

$$C_{corr} = (C - 32500) \frac{t_{int}}{t_{int} - N_B t_B} + 32500 \quad (2.22)$$

where  $t_{int}$  is the nominal integration period of 0.00355 seconds,  $N_B$  is the effective number of blanking pulses during an integration period, and  $t_B$  is the blanking duration. The corrected Earth count  $C_{corr}$  is then used to compute  $T_a$ .

## 2.2 ANTENNA PATTERN CORRECTION

Corrections of the calibrated antenna temperatures are performed following the radiometric calibration in order to transform calibrated antenna temperature to brightness temperature. The antenna pattern correction involves first correcting for the antenna spillover.

For vertical polarized channels:

$$T_a^{v1} = T_a / \eta_v - T_c(1 - \eta_v) / \eta_v \quad (2.23)$$

For horizontal polarized channels:

$$T_a^{h1} = T_a / \eta_h - T_c(1 - \eta_h) / \eta_h \quad (2.24)$$

where  $T_a$  is the measured antenna temperature,  $\eta_v$  and  $\eta_h$  are the spillover coefficients for V and H channels, and  $T_c$  is the radiometric temperature of cold space, corrected for the approximation to the Rayleigh-Jeans law. Values of  $T_c$  for each channel are given in Table 2.5.  $\eta_v$  and  $\eta_h$  for all channels are given in Table 2.11.

**Table 2.11. Coefficients for computing APC.**

f [GHz]	10.65	18.7	23.8	36.64	89	166	183.31
$a_{vh}$	0.00290	0.00235	0.00167	0.00120	0.00145	0.01339	0.01104
$a_{hv}$	0.00290	0.00235	N/A	0.00120	0.00145	0.01339	N/A
$\eta_v$	0.95729	0.95924	0.97358	0.99598	0.99726	0.98885	0.99239
$\eta_h$	0.95729	0.95924	N/A	0.99598	0.99726	0.98885	N/A
$1 - \eta_v$	0.04271	0.04076	0.02642	0.00402	0.00274	0.01115	0.00761
$1 - \eta_h$	0.04271	0.04076	N/A	0.00402	0.00274	0.01115	N/A
$\lambda$	N/A	N/A	1.02610	N/A	N/A	N/A	1.00767
$\xi$	N/A	N/A	0.223	N/A	N/A	N/A	-0.037
R	1.00000	1.00000	1.00000	1.00000	1.00000	1.00000	1.00000

Secondly, the APC corrects for the emissivity of the reflector.

$$T_a^v = T_a^{v1}/R + T_{refl}(1 - R)/R \quad (2.25)$$

$$T_a^h = T_a^{h1}/R + T_{refl}(1 - R)/R \quad (2.26)$$

where  $R$  is the RF reflectivity of the main reflector, and  $T_{refl}$  is the measured temperature of the reflector. The values of  $R$  are given in Table 2.8. Since  $R=1$ :

$$T_a^v = T_a^{v1} \quad (2.27)$$

$$T_a^h = T_a^{h1} \quad (2.28)$$

Thirdly, the APC corrects for the cross-polarization:

$$T_b^v = ((1 - a_{hv}) T_a^v - a_{vh} T_a^h) / (1 - a_{hv} - a_{vh}) \quad (2.29)$$

$$T_b^h = ((1 - a_{vh}) T_a^h - a_{hv} T_a^v) / (1 - a_{hv} - a_{vh}) \quad (2.30)$$

Values of  $\mathbf{a}_{hv}$  and  $\mathbf{a}_{vh}$  are given in Table 2.8. Substitute equations (2.24) to (2.28) to equations (2.29) and (2.30), and we can get:

$$\mathbf{T}_b^v = \mathbf{C}_n^v \mathbf{T}_a^v - \mathbf{D}_n^v \mathbf{T}_a^h - \mathbf{E}_n^v \quad (2.31)$$

$$\mathbf{T}_b^h = \mathbf{C}_n^h \mathbf{T}_a^h - \mathbf{D}_n^h \mathbf{T}_a^v - \mathbf{E}_n^h \quad (2.32)$$

where

$$\mathbf{C}_n^v = (\mathbf{1} - \mathbf{a}_{hv}) / (\eta_v(1 - \mathbf{a}_{hv} - \mathbf{a}_{vh}))$$

$$\mathbf{D}_n^v = \mathbf{a}_{vh} / (\eta_h(1 - \mathbf{a}_{hv} - \mathbf{a}_{vh}))$$

$$\mathbf{E}_n^v = \mathbf{T}_c[(1 - \eta_v)(1 - \mathbf{a}_{hv}) / \eta_v - (1 - \eta_h) \mathbf{a}_{vh} / \eta_h] / (1 - \mathbf{a}_{hv} - \mathbf{a}_{vh})$$

$$\mathbf{C}_n^h = (\mathbf{1} - \mathbf{a}_{vh}) / (\eta_h(1 - \mathbf{a}_{hv} - \mathbf{a}_{vh}))$$

$$\mathbf{D}_n^h = \mathbf{a}_{hv} / (\eta_v(1 - \mathbf{a}_{hv} - \mathbf{a}_{vh}))$$

$$\mathbf{E}_n^h = \mathbf{T}_c[(1 - \eta_h)(1 - \mathbf{a}_{vh}) / \eta_h - (1 - \eta_v) \mathbf{a}_{hv} / \eta_v] / (1 - \mathbf{a}_{hv} - \mathbf{a}_{vh})$$

Equations (2.31) and (2.32) can be combined into equation (2.33):

$$\mathbf{T}_b = \mathbf{C}_n \mathbf{T}_a - \mathbf{D}_n \mathbf{T}_a^* - \mathbf{E}_n \quad (2.33)$$

$\mathbf{T}_a^*$ : Antenna temperature of cross-polarized channel of the  $\mathbf{T}_a$ .

For 23 GHz and 183 GHz channels, there are no cross-polarized channels; equation (2.33) is simplified to:

$$\mathbf{T}_b = \mathbf{C}_n \mathbf{T}_a - \mathbf{E}_n$$

The value of  $\mathbf{C}_n$  and  $\mathbf{E}_n$  for these channels is given in Table 2.12.

$\mathbf{C}_n = \lambda$ ,  $\mathbf{E}_n = -\xi$ , for each corresponding channel.

Table 2.12. Comparison of APC coefficients between V04 and V03.

Channel Number	Frequency GHz	$\mathbf{C}_n$		$\mathbf{D}_n$		$\mathbf{E}_n$	
		V03	V04	V03	V04	V03	V04
1	10.65 V	1.062802	1.052007	0.003875	0.003833	0.161459	0.131997
2	10.65 H	1.063577	1.052039	0.003904	0.003864	0.163503	0.131997
3	18.7 V	1.067189	1.048938	0.002993	0.002946	0.176538	0.126479
4	18.7 H	1.066024	1.049064	0.003125	0.003027	0.172972	0.126479
5	23.8 V	1.033860	1.028810	0.000000	0.000000	-0.282590	-0.295000
6	36.64 V	1.005063	1.005618	0.000946	0.000946	0.011610	0.013174
7	36.64 H	1.005063	1.005618	0.000946	0.000946	0.011610	0.013174
8	89.0 V	1.003099	1.003863	0.001195	0.001196	0.006225	0.008721
9	89.0 H	1.003099	1.003863	0.001195	0.001196	0.006225	0.008721
10	166.0 V	1.013758	1.025926	0.013758	0.013924	0.000000	0.053170
11	166.0 H	1.013758	1.025926	0.013758	0.013924	0.000000	0.053170
12	183 ± 3	1.000000	1.007940	0.000000	0.000000	0.000000	0.038000
13	183 ± 7	1.000000	1.007940	0.000000	0.000000	0.000000	0.038000

In addition to the APC, the antenna effect on the Earth view along-scan bias has been derived from data produced by Remote Sensing Systems together with data from the cold space maneuver, and the correction is applied in the algorithm. The antenna effect is subdivided into two terms: an additive term and a multiplicative term. The additive portion most likely comes from the backlobes for the 10-23 GHz channels, while the multiplicative term comes from edge-of-scan effects such as the cold sky reflector multi-layer insulation (MLI) intruding into the sidelobes of the feeds. The correction is performed on the calibrated brightness temperatures (after the antenna pattern correction), and is represented as:

$$T_{b\text{-corr}} = T_b - \Delta T_{\text{const}} - (T_{\text{intru}} - T_b) \Delta t_{\text{multi}} \quad (2.34)$$

where

$T_b$  is the calibrated brightness temperature.

$\Delta T_{\text{const}}$  is the constant along-scan bias term and can be found in Appendix D.

$T_{\text{intru}}$  is the temperature of the intrusion in Table 2.13.

$\Delta t_{\text{multi}}$  is the multiplicative bias term (units of K/K) and can be found in Appendix E.

**Table 2.13. Values for  $T_{\text{intru}}$  for each GMI channel.**

	10 V	10 H	18 V	18 H	23 V	36 V	36 H	89V	89H	166V	166H	183VA	183VB
$T_{\text{intru}}$	175	175	175	175	175	125	125	0	0	0	0	0	0

Figure 2.13 demonstrates the correction for 10 GHz V (upper panel) and 10 GHz H (lower panel) channels. Typically, the correction has significant effects on samples near the edge of the scan. The correction is after the magnetism corrections described in Section 2.4, and therefore both curves in the figures are already corrected for errors induced by magnetism.

**Figure 2.13. Along-scan correction on  $T_b$  for 10 GHz channels. Red line: un-corrected, Black line: corrected.**

### 2.3 INPUT, OUTPUT, AND ALGORITHM FLOWCHART

The input files for calibration include three consecutive L1A files and external tuning files. The L1A includes already geolocated Earth counts, and SC and HK telemetry for the designed time period. There is one L1A file immediately before the processing orbit and one L1A file immediately after for the best multi-scan calibration. The tuning file will include all externally determined data such as APC coefficients and hot load PRT weights. Key input parameters are listed in Table 2.14, and the flow diagram of GMI calibration is displayed in Figure 2.14.

The key output parameters include geolocated and calibrated  $T_a$  and  $T_b$ , as well as parameters required by higher level algorithms such as incidence angle, Sun glint angle, etc. The details of output parameters are presented in separate documents: GMI Base File Specification, and GMI L1B File Specification.

Table 2.14. Key input parameters.

Parameter	Dimension	Unit	Description	Source
Noise Diode Indicator	$n_{scans}$		All Scans	SC Packets
Earth View Count	$n_{chan}, n_{scans}, n_{pixels}$	Counts	All Scans	SC Packets
Hot Load Count	$n_{chan}, n_{scans}, n_{hsample}$	Counts	Every Other Scan	SC Packets
Cold Load Count	$n_{chan}, n_{scans}, n_{csample}$	Counts	Every Other Scan	SC Packets
Hot Load + Noise Diode Count	$n_{chan}, n_{scans}, n_{hsample}$	Counts	Every Other Scan	SC Packets
Cold Load + Noise Diode Count	$n_{chan}, n_{scans}, n_{csample}$	Counts	Every Other Scan	SC Packets
Hot Load Temperature	$11, n_{scans}$	Kelvin	All Scans	SC Packets
Cold Sky Temperature	$n_{chan}, n_{scans}$	Kelvin	All Scans	Tuning Data
Hot Load Tray Temperature	$n_{scans}$		All Scans	SC Packets
APC Coefficients	$3, n_{chan}$		All Scans	Tuning Data
Nonlinearity	$3, n_{chan}$	Kelvin	All Scans	Tuning Data
Correction Tables	$n_{chan}, n_{pixels}$		All Scans	Tuning Data

Figure 2.14. Flow chart of GMI L1B calibration process.

The algorithm is written in C. The code design is demonstrated in Table 2.15.

**Table 2.15. L1B code design.**

main.c	Call getCommandLine.c to get input and output file information. Check all input files; if OK and not empty, call doScan.c. Close all files.
doScans.c	Call readTune.c, collectCalibrationData.c to collect calibration data. Start Loop to all scans: Call getScan.c to collect scan telemetry data. Call process.c to process the scan.
process.c	Call getSwath1.c and getSwath2.c to put geolocation data and L1A counts into the output data structure. Call missl1b.c to assign missing values for the rest of the output data structure. If the scan is not a missing scan: Call calscan.c to perform calibration and fill all output data structure. Call writescan.c to write out the output data into the output HDF file.
calscan.c	Perform radiometric calibration. If it is for GMIBASE, fill out all GMIBASE data structure. If it is for 1BGMI, call antencorr.c to perform antenna pattern correction and fill out all 1BGMI data structure.

## 2.4 DEEP-SPACE MANEUVER AND CORRECTION ON ERROR INDUCED BY MAGNETIC FIELD

During the deep-space maneuver, it was found that the GMI receivers exhibit a small but detectable variation in output when exposed to a changing magnetic field. Each receiver exhibits the variation due to the Earth's magnetic field, observatory magnetic fields, and instrument magnetic fields. The magnetometers on the spacecraft directly measure the magnetic field from the Earth and spacecraft, which provides means for a correction of those terms. The combined Earth and spacecraft magnetic field cause a one-cycle sinusoid across the full 360-degree scan. As for the instrument magnetic fields, two main sources of magnetic field have been identified: 1) spin mechanism, and 2) feed switches on the launch restraints. The spin mechanism causes a small ripple in the counts at 96 cycles per revolution. The reed switches on the launch restraints cause blips in the scan as the receivers pass the launch restraints. The blips are most noticeable at the 10 GHz H-pol channel, the receiver closest to the Instrument Bay System (IBS) launch restraints, although they can also be seen in other channels. The change in receiver output due to instrument magnetic fields has now been shown to exist in GMI ground data and has been very stable from ground to on-orbit.

The magnetic correction is applied to the full-scan radiometer counts prior to calibration and has the following form:

$$C_{\text{corr}} = C - \mathbf{S} \cdot \mathbf{B} - \gamma \quad (2.35)$$

$C_{\text{corr}}$  represents the corrected counts from the receiver.

$C$  represents the uncorrected counts from the receiver.

The vector  $\mathbf{B}$  is the magnetic field vector. The vector  $\mathbf{S}$  is the susceptibility vector.

And  $\gamma$  is a look-up table sample-dependent bias that captures the variations due to the magnetics of the instrument; it is provided in Appendix F.

Or we can rewrite equation (2.35) as equation (2.36) by separating magnetic field  $\mathbf{v}_{\text{mag}}$  and scan angle  $\theta$ :

$$C_{\text{corr}} = C - \alpha(\mathbf{v}_{\text{mag}})\cos(\theta) - \beta(\mathbf{v}_{\text{mag}})\sin(\theta) - \delta(\mathbf{v}_{\text{mag}}) - \gamma \quad (2.36)$$

$\mathbf{v}_{\text{mag}}$  is the voltage output vector (x, y, z).

$\theta = 0.6912 * i$  is the scan angle of the sample;  $i$  is full-scan sample index starting at 1 and progressing to 500.

Dot coefficients  $\alpha(\mathbf{v}_{\text{mag}})$ ,  $\beta(\mathbf{v}_{\text{mag}})$ , and  $\delta(\mathbf{v}_{\text{mag}})$  are dependent upon whether magnetic fields derived from magnetometers on the spacecraft or derived from another source of Earth's magnetic field are used.

When using a GPM Three-Axis Magnetometer (TAM) reading from the spacecraft, the  $\mathbf{V}_{\text{mag}}$  (in volts) components are:

$$V_x = -15.0 + 0.007326 \times V_{\text{Counts}}(x)$$

$$V_y = -15.0 + 0.007326 \times V_{\text{Counts}}(y)$$

$$V_z = -15.0 + 0.007326 \times V_{\text{Counts}}(z)$$

and

$$\alpha(\mathbf{v}_{\text{mag}}) = \mathbf{V}_{\text{mag}} \cdot \mathbf{S}_a = V_x * S_a(x) + V_y * S_a(y)$$

$$\beta(\mathbf{v}_{\text{mag}}) = \mathbf{V}_{\text{mag}} \cdot \mathbf{S}_b = V_x * S_b(x) + V_y * S_b(y)$$

$$\delta(\mathbf{v}_{\text{mag}}) = 0.0$$

Magnetic susceptibility vectors  $\mathbf{S}_a$  and  $\mathbf{S}_b$  are provided by BATC are shown in the following tables (Table 2.16 and Table 2.17):

**Table 2.16. BATC susceptibility vector  $\mathbf{S}_a$ .**

$\mathbf{S}_a$	Channels

The final implementation uses the Earth's magnetic fields based on International Geomagnetic Reference Field (IGRF) 2011 software and data. The major reason for this decision is that the GPM realtime system doesn't have the input of magnetometer readings at the processing time and that the correction using IGRF 2011 is slightly better. The susceptibility vector **S** in Table 2.16 is derived based on the IGRF 2011 magnetic field. However, the corrections using TAM data are tested and results are also evaluated.

When using the Earth's magnetic field based on IGRF 2011:

First we compute the volts from the Earth's magnetic field by  $V_{volts} = 0.0001 * V_{earthmag}$ .

We rotate the  $V_{volts}$  two times to transform the  $V_{volts}$  from the Earth-Centered, Earth-Fixed (ECEF) coordinate system into the GPM flight axes **Bs** (Geolocation Toolkit ATBD).

The susceptibility vectors **S** are provided by RSS and are shown in Table 2.18.

**B= R · Bs** where:

$$\begin{matrix} \cos(\theta) & \sin(\theta) & 0 \\ -\sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{matrix} \quad \begin{matrix} Vx \\ Vy \\ Vz \end{matrix}$$

**R** and **Bs**

Using equation (2.35), we get:

$$C_{corr} = C - (S_x(V_x \cos(\theta) + V_y \sin(\theta)) + S_y(-V_x \sin(\theta) + V_y \cos(\theta)) + S_z V_z) - \gamma$$

or:

$$\alpha(v_{mag}) = S_x V_x + S_y V_y$$

$$\beta(v_{mag}) = S_x V_y - S_y V_x$$

$$\delta(v_{mag}) = S_z S_z$$

for equation (2.36).

The following figures show the corrections of errors induced by a magnetic (MAG) field for a deep-space maneuver orbit. Figure 2.15 compares the magnetic fields from GPM housekeeping data (TAM reading) and from IGRF 2011. The results are consistent in the coordinate system. The contribution of the spacecraft to the total magnetic field is small.

**Figure 2.15. Magnet volts from Earth's magnetic fields and GPM TAM.**

Figure 2.16 shows along-track and along-scan variations before and after magnetism corrections. The along-track anomalies of 10 GHz V resemble the X-components of a magnetic field before correction. The along-track anomalies of the 10 GHz H channel are out of phase with the X-components of a magnetic field before correction. These variations are gone after magnetism corrections. The along-scan biases induced by a magnetic field are corrected for  $T_a$ . However, the along-scan biases due to antenna patterns are not corrected for  $T_a$ . These biases are large near the edges of scans. They are corrected in  $T_b$  (Figure 2.17). Figure 2.18 to Figure 2.29 demonstrate the magnetism and along-scan corrections for all other channels.

## 2.5 POST-LAUNCH VALIDATION

In addition to the validation described in Section 2.2 and Section 2.4, analyses are performed to compare biases between the current production version (V03B) and an earlier version (V03A) of production for the period when data are available.

V03B corrects the scan biases seen in many of the channels, most notably in 10.65H. The corrections added to V03B are combinations of magnetism correction described in Section 2.4 and along-scan antenna pattern correction described in Section 2.2. Figure 2.30 shows the scan biases for the nine low-frequency channels. The scan biases are shown as single differences (SDs) using the vicarious cold calibration method. Single differences calculated using GMI 1C V03A are shown in blue, and SDs using V03B are shown in red.

**Figure 2.30. Vicarious cold calibration single differences by scan position for V03A (blue) and V03B (red). V03B scan biases show less variation across the scan than V03A, most notably for 10.65H.**

V03B also corrects for the magnetic anomaly in the data that appears when splitting the data by yaw orientation and ascending/descending orbits. Figure 2.31 shows the vicarious cold calibration single differences, shown as the ascending SD minus the descending SD at each yaw orientation. This value should ideally be zero; however, some channels show a discrepancy using the V03A data. This is most obvious at 36.5V. V03B corrects for this discrepancy, reducing it to <0.1 K.

**Figure 2.31.** Ascending – descending SDs by yaw orientation for V03A (blue) and V03B (red). V03B reduces the discrepancy between the ascending and descending SDs, most notably at 36.5V.

**Figure 2.32. GMI  $T_b$  changes from V03 to V04.**

The Noise Equivalent Delta Temperature (NEDT) for cold load counts for the 13 GMI channels is shown in Figure 2.33. Values before orbit number 720 are those derived from the at-launch version of products, and values thereafter are those derived from the after-launch adjustments. For cold counts, the adjustment reduced NEDT significantly for channels 3-9. The adjustment does not affect the hot load NEDT significantly (Figure 2.34).

**Figure 2.33. Cold load NEDT for 13 GMI channels.**

**Figure 2.34. Hot load NEDT for 13 GMI channels.**

BATC provided on-orbit NEDT computation code using data from the hot load for trending purposes. The NEDT is subdivided into two main components: the random “white” noise component and the gain drift. The method of computing the white noise component is via the single-sample Allan standard deviation, which can be computed by first differencing neighboring calibrated hot load samples and then taking the root mean square (RMS) of the differences divided by the square root of 2:

$$\sigma_{T-Allan} = \left( \frac{1}{2N_{scans}(h2-h1)} \sum_{j=1}^{N_{scans}} \sum_{i=h1+1}^{h2} (T_h(i, j) - T_h(i-1, j))^2 \right)^{1/2}$$

where  $N_{scans}$  is the total number of valid scans over which the NEDT is computed (for channels with noise diodes,  $N_{scans}$  is the total number of valid scans with noise diodes OFF),  $h1$  is the starting sample of the hot load,  $h2$  is the end sample of the hot load,  $i$  is the sample index,  $j$  is the scan index of all scans over which the NEDT is computed (for channels with noise diodes, it is the index to all scans with noise diodes OFF over which the NEDT is computed), and  $T_h(i, j)$  is the antenna temperature of the hot load for sample  $i$  and scan  $j$ . In order to reduce the uncertainty of the calculation, it is suggested that  $N_{scans}$  represent an orbit of data.

From the Allan standard deviation, the system noise temperature of the channel is computed as follows:

$$T_{\text{sys}} = \sigma_{T-\text{Allan}} \sqrt{B\tau}$$

where  $B$  is the channel bandwidth in Hz and  $\tau$  is the integration period in seconds, which is 0.00355 seconds for all GMI channels. Further, the receiver noise temperature can be computed:

9.652E+7 9.493E+7 1.9383E+8 1.9448E+8 3.6787E+8 6.9840E+8 7.0753E+8 2.93317E+9  
2.96033E+9 1.92600E+9 1.94783E+9 1.35767E+9 1.87867E+9

$$T_{\text{rcvr}} = T_{\text{sys}} - \langle T_h \rangle$$

where  $\langle T_h \rangle$  represents the average hot load temperature over the duration of  $N_{\text{scans}}$ . The total NEDT (including gain drift) is:

$$\text{NEDT} = \frac{1}{\eta_p} \left( \frac{1}{N_{\text{scans}}(h2-h1+1)} \sum_{j=1}^{N_{\text{scans}}} \sum_{i=h1}^{h2} \left( \frac{300K + T_{\text{rcvr}}}{T_{h-b}(j) + T_{\text{rcvr}}} \right)^2 (T_h(i, j) - T_{h-b}(j))^2 \right)^{1/2}$$

where  $\eta_p$  is the spillover coefficient (which references the data to the reflector aperture), and  $\bar{T}_h(j)$  is the hot load brightness temperature at scan  $j$ . The term  $(300K + T_{\text{rcvr}}) / (\bar{T}_h(j) + T_{\text{rcvr}})$  scales the NEDT to an equivalent 300K input antenna temperature.

## **11. APPENDIX G. CHANGES FROM VERSION 03 TO VERSION 04**

The following describes the changes from Version 03 (V03) GMI L1B/Base to Production Version 04 (V04) GMI L1B/Base.

### **CALIBRATION**

1. Adjustment of spillover coefficients of all GMI channels. This adjustment is the major improvement from V03 to V04 in GMI antenna pattern correction (APC). The adjustment of spillover is based on the data from GMI inertial hold and refinements of the analysis performed by the GMI manufacturer. Table 2.12 shows comparisons of APC coefficients reflecting the changes due to spillover adjustments.  $T_b$  changes vary from channel to channel and are functions of brightness temperatures. Figure 2.32 demonstrates the  $T_b$  changes for all channels in their normal temperature range. For channels 1-5,  $T_b$  reduced  $\sim 3 - 6$  K at their maximums. For channels 10-13,  $T_b$  increased  $\sim 2 - 4$  K at their maximums. For channels 6-9,  $T_b$  increased  $\sim 0.1$  K at their maximums.
2. Adjustment of antenna-induced along-scan bias correction. This is a minor adjustment and may result in  $T_b$  changes of less than 0.1 K.
3. Adjustment of magnetic correction coefficients. This is also a minor adjustment and may result in  $T_b$  changes of less than 0.1 K.

All of these corrections are implemented in V04 GMI L1B/Base as well as ITE043 and ITE057. There were no code adjustments for these updates.

### **GEOLOCATION**

There are no pixel geolocation changes between Versions 03 and 04; however, there is a notable change affecting Sun angles. This change is due to the correction of a typographical error in the calculation of Sun angle in the V03 Geolocation Toolkit code, which causes maximum error of about 6 degrees in the vector directions, reported solar beta angles, and Sun glint angles. This significant change was implemented on December 4, 2014, for V03 processing. This implementation resulted in a change of the V03 GMI L1B/Base version from V03B to V03C. The correction is included in the GMI L1B/Base V03C and ITE043 data from December 4, 2014, but is not included in the V03B and ITE043 data before December 4, 2014.

Another bug in computation of Sun glint angles in the V03 Geolocation Toolkit was discovered and corrected in the V04 Geolocation Toolkit. This was due to a bug in the code that rejected computing Sun glint angle when a scan time coincidence was at noon UT. This error has a very remote chance of occurring with a scan time coincidence at noon UT within microseconds.

All of these Geolocation Toolkit corrections are implemented in V04 GMI L1B/Base and in ITE057.

### **OTHERS**

NEDT computation was added to the GMIBase code, and the data format was revised to include the NEDT parameter.

## **12. APPENDIX H. CHANGES FROM VERSION 04 TO VERSION 05**

This chapter of the GMI L1B ATBD describes the calibration changes from PPS production Version 04 (V04) GMI L1B/Base to future PPS Production Version 05 (V05) GMI L1B/Base. All data source are from the Data calibration handbook revision H. The analysis that led to the revision H handbook were undertaken at RSS and Ball. The details of this analysis can be found in the paper by Wentz and Draper (2016). *See references for citation details.*

Data and methods were analyzed and verified by the X-cal team before they authorized PPS to implement the following final calibration changes for V05.

### **CALIBRATION**

The PPS V05 GMI calibration updates include adjustments of spillover coefficients for all GMI channels (these have a major impact on  $T_b$ ) and a number of other minor adjustment described below. The magnitudes of  $T_b$  changes can be seen in Figure 12.1. The  $T_b$ s are reduced around 1 K at  $T_b$  around 280 K for channels 1-5. These changes are dominated by antenna pattern correction (APC) revisions.  $T_b$  changes for other channels are minor.

**Figure 12.1. GMI  $T_b$  changes from V04 to V05.**

1. Adjusted spillover coefficients of all GMI channels. This adjustment is the major improvement from V04 to V05 in GMI antenna pattern correction. The adjustment of spillover is based on the data from GMI deep space maneuver, inertial hold, and refinements

of the analysis performed by the RSS and Ball (Wentz and Draper 2016). The results are analyzed and approved by the GPM Intercalibration Working Group (X-CAL). The new spillover coefficients are shown in Table 12.1. Table 12.2 shows comparisons of APC coefficients between V04 and V05, reflecting the changes due to spillover adjustments.  $T_b$  changes vary from channel to channel and are functions of brightness temperatures.

**Table 12.1. Coefficients for computing APC in V05.** (This table supersedes Table 2.11 in Section 2.2.)

2. Adjusted cold load temperature for 10 GHz channels (Table 12.3). This is a minor adjustment and may result in  $T_b$  changes of less than 0.2 K for 10 GHz channels.

**Table 12.3. Mean cold sky temperature  $T_c$  for all GMI channels in V05. (This table supersedes Table 2.5 in Section 2.1.)**

Frequency (GHz)	10.65	18.7	23.8	36.64	89.0	166.0	183.31
Cold Load Temperature	2.94	2.85	2.77	2.82	3.27	4.43	4.76

3. Added a count adjustment (Table 12.4) in the magnetism correction equation. This is a minor adjustment and may result in  $T_b$  changes of less than 0.2 K.

**Table 12.4. Correction of count biases.**

Channel	Earth	Hot	Cold
	$\Delta Ce$	$\Delta Ch$	$\Delta Cc$
10 V	8.8	0	0
10 H	3.2	0	0
18 V	5.1	0	-2.7
18 H	0.4	0	-2.7
23 V	5.5	0	-5.5
36 V	0.3	0	-1.4
36 H	2.6	0	-1.4
89 V	0.8	0	-0.8
89 H	0.8	0	-2.7
166 V	0	0	0
166 H	0	0	0
183 VA	0	0	0
183 VB	0	0	0

4. Adjusted magnetic correction coefficients. This is also a minor adjustment and may result in  $T_b$  changes of less than 0.2 K.

**Table 12.5. RSS susceptibility vector S. (This table supersedes Table 2.18 in Section 2.4.)**

Channel	Sx	Sy	Sz
1	2.843e+00	-2.72e+00	0.0e00
2	-4.117e+00	2.622e+00	0.0e00
3	6.25e-01	4.6e-02	0.0e00
4	-2.396e+00	-2.526e+00	0.0e00
5	2.089e+00	1.132e+00	0.0e00
6	3.398e+00	-4.991e+00	0.0e00
7	1.29e+00	-1.806e+00	0.0e00
